## Abstract

*Keywords:* multiproduct batch, processing time maximization

---

## 1. Introduction

The literature presents several scientific papers that address the multiproduct batch problem. Most works target the problem of multiproduct batch scheduling (MPBS), in which it is necessary to determine the ideal batch size for each product, in a production of several products, which share the same production facilities and for which demand is known (Eilon, 1985). In this work, we are concerned with determining the ideal processing time for a batch consisting of a set of products, each product being or not different from the other products of the same batch. That is, we consider a specific case where different products are processed simultaneously on the same processor. This case occurs, for example, during the processing of plastic bags in extruders. In this process, the resins are melted, then the molten resin passes through a cylinder forming a balloon and this balloon, after cooling, will be stored in a coil. This coil, in turn, will be cut into several coils, forming different models of plastic bags.

## 2. Multiproduct batch processing time maximization problem

The multiproduct batch processing time maximization problem arises when a set of different products are processed simultaneously in the same production batch. In this problem, it is considered that the quantity produced of each product is directly proportional to the processing time, however, with a different production rate (quantity/unit of time) for each prod-

uct. In addition, there is a maximum quantity allowed for the production of batch products, defined both individually and for the set. The maximum production quantity of each product is defined according to the demand for the product. However, it is still possible to stock the products and/or send them to the outlets. In both cases, there is a stocking/shipping limit for each product and a stocking/shipping limit for the set of products in the batch. Also, there is a time limit available for processing the batch. The problem consists of defining the maximum processing time for the batch, respecting the limitations related to the quantities produced. For a better understanding of the problem, an example is presented below.

*Example:* A certain machine must process a batch containing 2 different products: A and B. The production rate of A is 60 g/min while the production rate of B is 40 g/min. The factory has free stock for a maximum of 3000 g of any product, and, according to the maximum stock allowed for each product, an additional 3000 g of product A and 2000 g of product B may be stocked at the factory. There is a demand for 1000 g of product A and 500 g of product B. The factory has an outlet that has free space in stock of 1000 g, which can receive a maximum of 600 g of each product. A maximum time of 100 minutes of this machine can be allocated for processing this batch. What is the maximum possible time for processing this batch ?

### 3. Mathematical model

Given that:

$UD_i$  is the demand for the product  $i$ ;

$I$  is the maximum quantity allowed for additional factory storage of all products in the batch;

$UI_i$  is the maximum quantity allowed for stocking the product  $i$  in the factory;

$O$  is the maximum quantity allowed for shipment of all products to outlets;

$UO_i$  is the maximum amount of product  $i$  that can be shipped to outlets;

$p_i$  is the production rate of product  $i$ ;

$Z$  is the timeout for batch processing;

$P_i$  is the amount of product  $i$  produced;

$D_i$  is the amount of product  $i$  delivered for the demand;

$O_i$  amount of product  $i$  shipped to factory outlets;

$I_i$  is the amount of product  $i$  that will be stored at the factory;

$T$  is the batch processing time.

We have the problem:

$$\max \quad T \tag{1}$$

*s.t.*

$$P_i - p_i * T = 0 \quad \forall i \tag{2}$$

$$P_i - D_i - O_i - I_i = 0 \quad \forall i \tag{3}$$

$$D_i \leq UD_i \quad \forall i \tag{4}$$

$$O_i \leq UO_i \quad \forall i \tag{5}$$

$$\sum_i O_i \leq O \tag{6}$$

$$I_i \leq UI_i \quad \forall i \tag{7}$$

$$\sum_i I_i \leq I \tag{8}$$

$$T \leq Z \quad (9)$$

$$D_i, O_i, I_i \in \mathbb{Z}^+ \quad \forall i \quad (10)$$

where:

Constraints in (2) relate the quantity produced,  $P_i$ , to batch processing time  $T$ . Constraints in (3) calculate the quantity produced,  $P_i$ , as a function of the primary variables,  $D_i$ ,  $O_i$  and  $I_i$ . Constraints in (4), (5), and (7) state that the quantity delivered to demand, the quantity shipped to the outlets, and the factory-stocked quantity of each product must be less than their respective known limits. Constraints (6) and (8) state that both the sum of product quantities sent to the outlets and the sum of product quantities stored in the factory must be less than their respective maximum allowed values. The restriction in (9) establishes that there is a batch processing time limit,  $Z$ , that must be respected. And finally, the constraints in (10) inform the nature of the decision variables.

#### 4. Analytical solution

It is possible to consider the factory stock and the outlets stock as single stock, so we have:

$$E_i = O_i + I_i \quad (11)$$

where  $E_i$  is the sum of the quantity stored at the factory and the quantity sent to the outlets of the product  $i$ .

So that:

$$E_i \leq \text{UO}_i + \text{UI}_i \quad (12)$$

and

$$\sum_i E_i \leq \text{O} + \text{I} \quad (13)$$

It is also possible to split the batch processing time into two time slots:

$$T = T' + T'' \quad (14)$$

and consider that  $T'$  is the maximum processing time used only for production that will meet the demand. Thus, we can find  $T'$ , solving the reduced problem:

$$\max \quad T' \quad (15)$$

*s.t.*

$$D_i - p_i * T' = 0 \quad \forall i \quad (16)$$

$$D_i \leq UD_i \quad \forall i \quad (17)$$

$$D_i \in \mathbb{Z}^+ \quad \forall i \quad (18)$$

This reduced problem can be rewritten in the form:

$$\max \quad T' \quad (19)$$

*s.t.*

$$T' \leq UD_i / p_i \quad \forall i \quad (20)$$

So we have that  $T'$  will be the smallest of the ratios  $UD_i / p_i$  of all products.

Once we find the value of  $T'$ , we can calculate the value of unmet demand for each product after  $T'$ ,  $S_i$ , through the equations in (22).

$$S_i = UD_i - p_i * T' \quad \forall i \quad (21)$$

Now we consider that the time interval  $T''$  will be used for the production of the quantities that will be stored (in the factory and in the outlets), as well as of the demand not met by the production in the first time interval,  $S_i$ .

In this case, we can find  $T'''$  by solving the second reduced problem:

$$\max T'' \quad (22)$$

*s.t.*

$$E_i - p_i * T'' = 0 \quad \forall i \quad (23)$$

$$E_i - S_i \leq UO_i + UI_i \quad \forall i \quad (24)$$

$$\sum_i E_i - S_i \leq O + I \quad (25)$$

$$E_i \in \mathbb{Z}^+ \quad \forall i \quad (26)$$

Again, using a little algebra, we can rewrite this reduced problem in the form:

$$\max T'' \quad (27)$$

*s.t.*

$$T'' \leq (UO_i + UI_i + S_i)/p_i \quad \forall i \quad (28)$$

$$T'' \leq (O + I + \sum_i S_i) / \sum_i p_i \quad (29)$$

So, being  $N$  the number of products in the batch, we will have  $N + 1$  inequalities that limit the value of  $T''$  by constants and again  $T''$  will be defined by the smallest value.

So the solution method can be decomposed into 4 steps:

step 1: find  $T'$ , where:

$$T' = \min_{\forall i} \{UD_i/p_i\} \quad (30)$$

step 2: calculate  $S_i$  for all products.

step 3: find  $T''$ , where:

$$T'' = \min\{\min_{\forall i}\{(UO_i + UI_i + S_i)/p_i\}, (O + I + \sum_i S_i) / \sum_i p_i\} \quad (31)$$

step 4: calculate  $T$ , where:

$$T = T' + T'' \quad (32)$$

$$T = \min\{T, Z\} \quad (33)$$

It is probably possible to extend this thinking to the solution of a class of linear optimization problems. However, we will work on this concept in an upcoming paper.

*Solution for the example presented before*

Applying the method for solving the example presented in section 2, we have:

$$T' \leq 1000g/60g/min$$

$$T' \leq 16,67min \quad \text{for A}$$

$$T' \leq 500g/40g/min$$

$$T' \leq 12,50min \quad \text{for B}$$

so:

$$T' = 12$$

Then:

$$S_A = 1000g - 12min * 60g/min = 280g$$

$$S_B = 500g - 12min * 40g/min = 20g$$

And so we have:

$$T'' \leq (3000g + 600g + 280g)/60g/min$$

$$T'' \leq 64,67min \quad \text{for A}$$

$$T'' \leq (2000g + 600g + 20g)/40g/min$$

$$T'' \leq 65,50min \quad \text{for B}$$

$$T'' \leq (1000g + 3000g + 300g)/100g/min$$

$$T'' \leq 43min \quad \text{for A and B}$$

So that:

$$T'' = 43min$$

So we have:

$$T = 55min$$

As  $T < Z=100$ , then this will certainly be the optimal solution.

In this case we will have:

$$P_A = 3300g \text{ e } P_B = 2200g$$

$$D_A = 1000g \text{ e } D_B = 500g$$

$$E_A = 2300g \text{ e } E_B = 1700g$$

Note that it is not important to know the values of  $O_i$  and  $I_i \forall i$  however these values can be found by taking a solution from the indeterminate system of inequations:

$$\sum_i O_i \leq 0 \tag{34}$$

$$\sum_i I_i \leq I \quad (35)$$

## 5. Tests and results

To test the developed model and analytical solution method, we created a solver in C++ and a solver in LINGO (both available at [github.com](https://github.com)). We tested the solvers developed for the benchmarks presented below.

$i$	1	2	total
$p_i$	60	40	
$UD_i$	1000	500	
$UO_i$	600	600	1000
$UI_i$	3000	2000	3000
			Z 100

Table 1: Benchmark MBPTMP 001

$i$	1	2	3	total
$p_i$	60	40	50	
$UD_i$	1000	500	800	
$UO_i$	600	600	600	1500
$UI_i$	3000	2000	1000	3500
				Z 100

Table 2: Benchmark MBPTMP 002

For building larger benchmarks, we used the following functions:

$$p_i = rand() \% 30 + 10 \quad (36)$$

$i$	1	2	3	4	5	6	7	8	9	10	total
$p_i$	60	40	50	40	30	50	60	10	20	40	
$UD_i$	1000	500	800	500	400	500	2000	300	500	1000	
$UO_i$	600	600	600	1500	300	200	500	800	0	200	3000
$UI_i$	3000	2000	1000	800	3000	1000	400	300	200	0	5000
										Z	100

Table 3: Benchmark MBPTMP 003

$$UD_i = rand() \% 3000 + 800; \quad (37)$$

$$O = rand() \% 3000 + 500; \quad (38)$$

$$UO_i = rand() \% (O - 500) + 500; \quad (39)$$

$$I = rand() \% 5000 + 1000; \quad (40)$$

$$UI_i = rand() \% (I - 1000) + 1000; \quad (41)$$

$$Z = 100; \quad (42)$$

Seeking to enable the reproduction of the results, in the computational construction of the benchmarks we used the function `srand((unsigned) source)`, where `source` is a defined value. To build the results presented in this work, we used `source=0`.

Table X presents a comparison of the results obtained by applying the analytical method and the LINGO solver for the solution of the previously presented benchmarks.

## 6. Contributions

The work for the elaboration of this paper is being carried out by three professors, as described below. Professor Fraga, T.B., was responsible for identifying the problem, mathematical modeling, proposing an analytical solution, developing a solver in C ++ for the analytical solution, developing benchmarks, and testing the analytical method and the solver in C++, as well as surveying bibliography and elaboration of the paper. Professor Henrique, M. is developing a solver in LINGO for testing and validating the model. Professor Menezes, R. is contributing to the bibliographic survey and to writing the bibliographic review presented in the paper.
